Elaborazione delle immagini (Image processing I)

academic year 2012-2013

Sharpening

- The term *sharpening* is referred to the techniques suited for enhancing the intensity transitions.
- In images, the borders between objects are perceived because of the intensity change: the crisper the intensity transitions, the sharper the image is perceived.
- The intensity transitions between adjacent pixels are related to the derivatives of the image.
- Hence, operators (possibly expressed as linear filters) able to compute the derivatives of a digital image are very interesting.

First derivative of an image

- Since the image is a discrete function, the traditional definition of derivative cannot be applied.
- Hence, a suitable operator have to be defined such that it satisfies the main properties of the first derivative:
 - 1. it is equal to zero in the regions where the intensity is constant;
 - 2. it is different from zero for an intensity transition;
 - 3. it is constant on ramps where the intensity transition is constant.
- The natural derivative operator is the difference between the intensity of neighboring pixels (spatial differentiation).
- ▶ For simplicity, the monodimensional case can be considered:

$$\frac{\partial f}{\partial x} = f(x+1) - f(x)$$

- Since \$\frac{\partial f}{\partial x}\$ is defined using the next pixel:
 it cannot be computed for the last pixel of each row (and column);
 - it is different from zero in the pixel before a step.

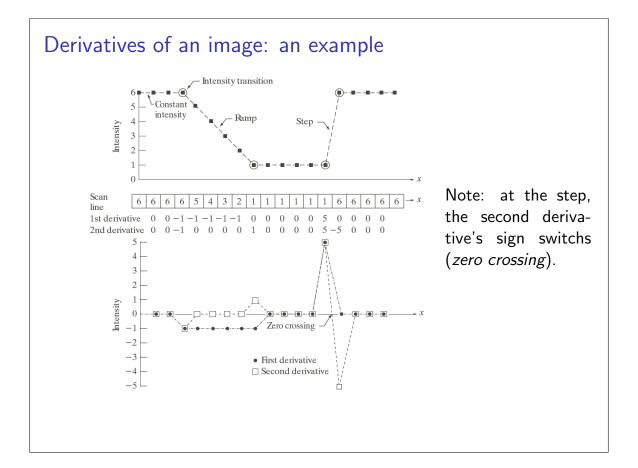

Second derivative of an image

Similarly, the second derivative operator can be defined as:

$$\frac{\partial^2 f}{\partial x^2} = f(x+1) - f(x) - (f(x) - f(x-1))$$

= f(x+1) - 2f(x) + f(x-1)

- This operator satisfies the following properties:
 - 1. it is equal to zero where the intensity is constant;
 - 2. it is different from zero at the beginning of a step (or a ramp) of the intensity;
 - 3. it is equal to zero on the constant slope ramps.
- Since $\frac{\partial^2 f}{\partial x^2}$ is defined using the previous and the next pixels:
 - it cannot be computed with respect to the first and the last pixels of each row (and column);
 - it is different from zero in the pixel that precedes and in the one that follows a step.

Laplacian Usually the sharpening filters make use of the second order operators. A second order operator is more sensitive to intensity variations than a first order operator. Besides, partial derivatives has to be considered for images. The derivative in a point depends on the direction along which it is computed. Operators that are invariant to rotation are called *isotropic*. Rotate and differentiate (or filtering) has the same effects of differentiate and rotate. The Laplacian is the simplest isotropic derivative operator (wrt. the principal directions):

Laplacian filter

In a digital image, the second derivatives wrt. x and y are computed as:

$$\frac{\partial^2 f}{\partial x^2} = f(x+1, y) - 2f(x, y) + f(x-1, y)$$

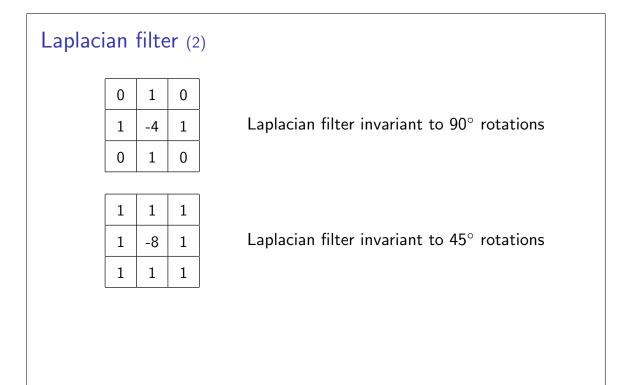

$$\frac{\partial^2 f}{\partial y^2} = f(x, y+1) - 2f(x, y) + f(x, y-1)$$

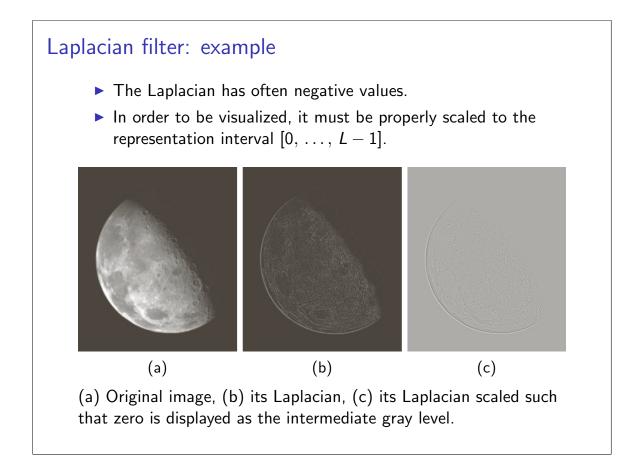

► Hence, the Laplacian results:

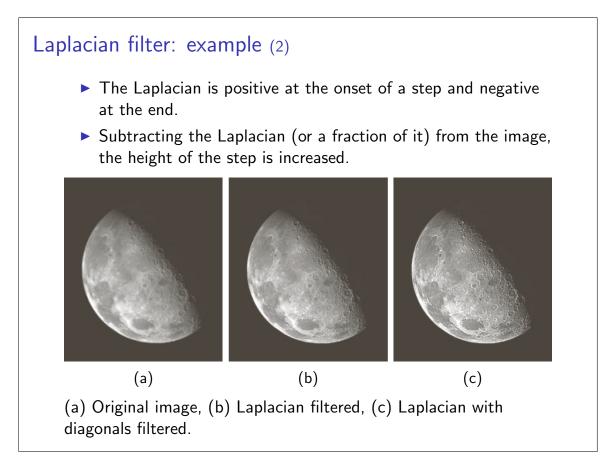

$$\nabla^2 f(x, y) = f(x+1, y) + f(x-1, y) + f(x, y+1) + f(x, y-1) - 4f(x, y)$$

► Also the derivatives along to the diagonals can be considered:

$$\nabla^2 f(x, y) + f(x-1, y-1) + f(x+1, y+1) + f(x-1, y+1) + f(x+1, y-1) - 4f(x, y)$$

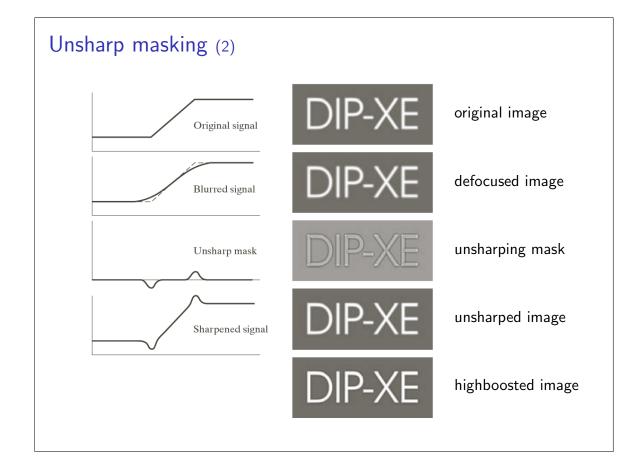

Unsharp masking

- The technique known as unsharp masking is a method of common use in graphics for making the images sharper.
- It consists of:
 - 1. defocusing the original image;
 - 2. obtaining the mask as the difference between the original image and its defocused copy;
 - 3. adding the mask to the original image.
- The process can be formalized as:

$$g = f + k \cdot (f - f * h)$$

where f is the original image, h is the smoothing filter and k is a constant for tuning the mask contribution.

• If k > 1, the process is called *highboost* filtering.

Gradient

- The gradient of a function is the vector formed by its partial derivatives.
- For a bidimensional function, f(x, y):

$$abla f \equiv \operatorname{grad}(f) \equiv \begin{bmatrix} g_x \\ g_y \end{bmatrix} = \begin{bmatrix} rac{\partial f}{\partial x} \\ rac{\partial f}{\partial y} \end{bmatrix}$$

- The gradient vector points toward the direction of maximum variation.
- ▶ The gradient *magnitude*, *M*(*x*, *y*) is:

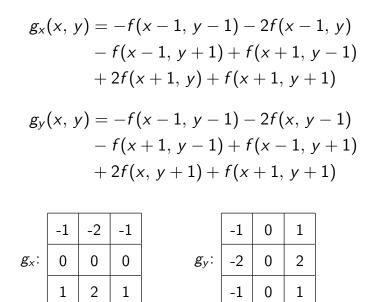

$$M(x, y) = \max(\nabla f) = \sqrt{g_x^2 + g_y^2}$$

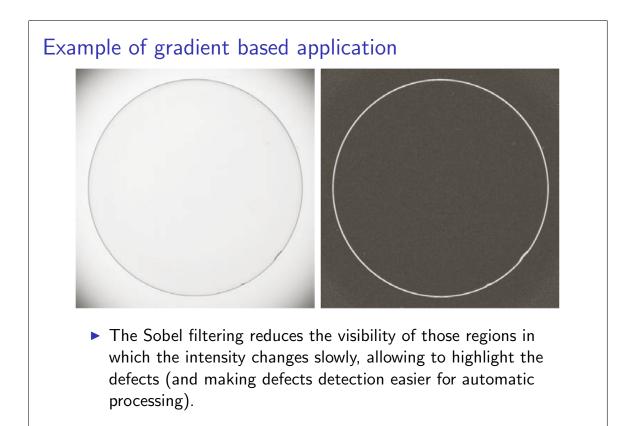

- It is also called gradient image.
- Often approximated as $M(x, y) \approx |g_x| + |g_y|$.

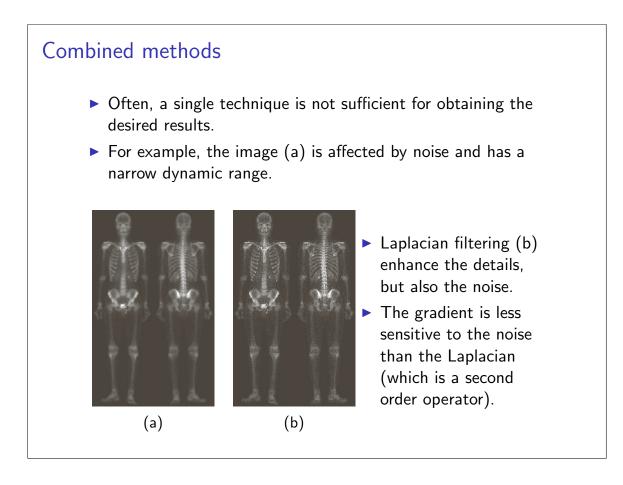

Derivative operators Basic definitions: $g_x(x, y) = f(x+1, y) - f(x, y)$ $g_{y}(x, y) = f(x, y+1) - f(x, y)$ g_y : $\begin{array}{c} -1 \\ 1 \end{array}$ g_x : -1 1 Roberts operators: $g_x(x, y) = f(x+1, y+1) - f(x, y)$ $g_{y}(x, y) = f(x, y+1) - f(x-1, y)$ 0 -1 0 -1 g_x : g_y : 1 1 0

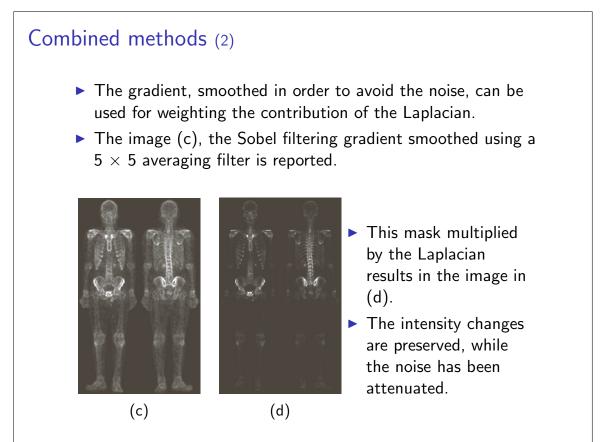

Derivative operators (2)

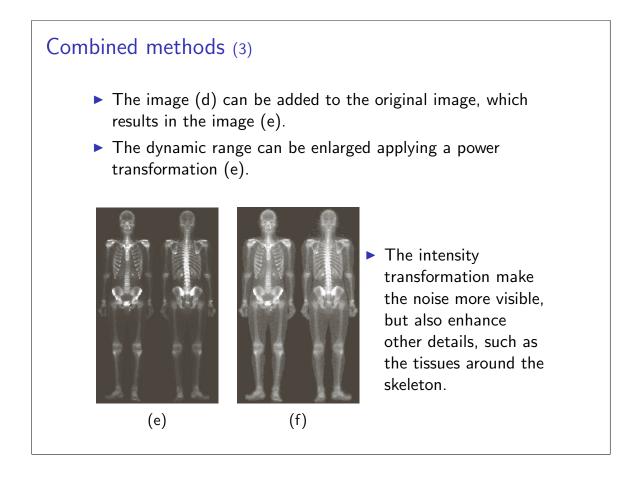

Sobel operators:

Bilateral Filtering * The image g is obtained from f, through bilateral filtering: $g(p) = \frac{1}{W_p} \sum_{q \in N_p} \exp\left(-\frac{||q - p||^2}{\sigma_s^2}\right) \exp\left(-\frac{||f(q) - f(p)||^2}{\sigma_i^2}\right) f(q)$ where W_p is the normalization factor: $W_p = \sum_{q \in N_p} \exp\left(-\frac{||q - p||^2}{\sigma_s^2}\right) \exp\left(-\frac{||f(q) - f(p)||^2}{\sigma_i^2}\right)$ and N_p is a suitable neighborhood of p. • What is the effect produced by the filter? • Notes: • when σ_i grows, the filter tends to an averaging filter; • the filter is not linear.
