# Classification methods

---

- Classification: Basic Concepts 
- Decision Tree Induction
- Bayes Classification Methods
- Support Vector Machines
- Model Evaluation and Selection
- *Rule-Based Classification*
- *Techniques to Improve Classification Accuracy: Ensemble Methods*

# Supervised vs. Unsupervised Learning

---

- Supervised learning (classification)
  - Supervision: The training data (observations, measurements, etc.) are accompanied by **labels** indicating the class of the observations
  - New data is classified based on the training set
- Unsupervised learning (clustering)
  - The class labels of training data is unknown
  - Given a set of measurements, observations, etc. with the aim of establishing the existence of classes or clusters in the data

# Prediction Problems: Classification vs. Numeric Prediction

---

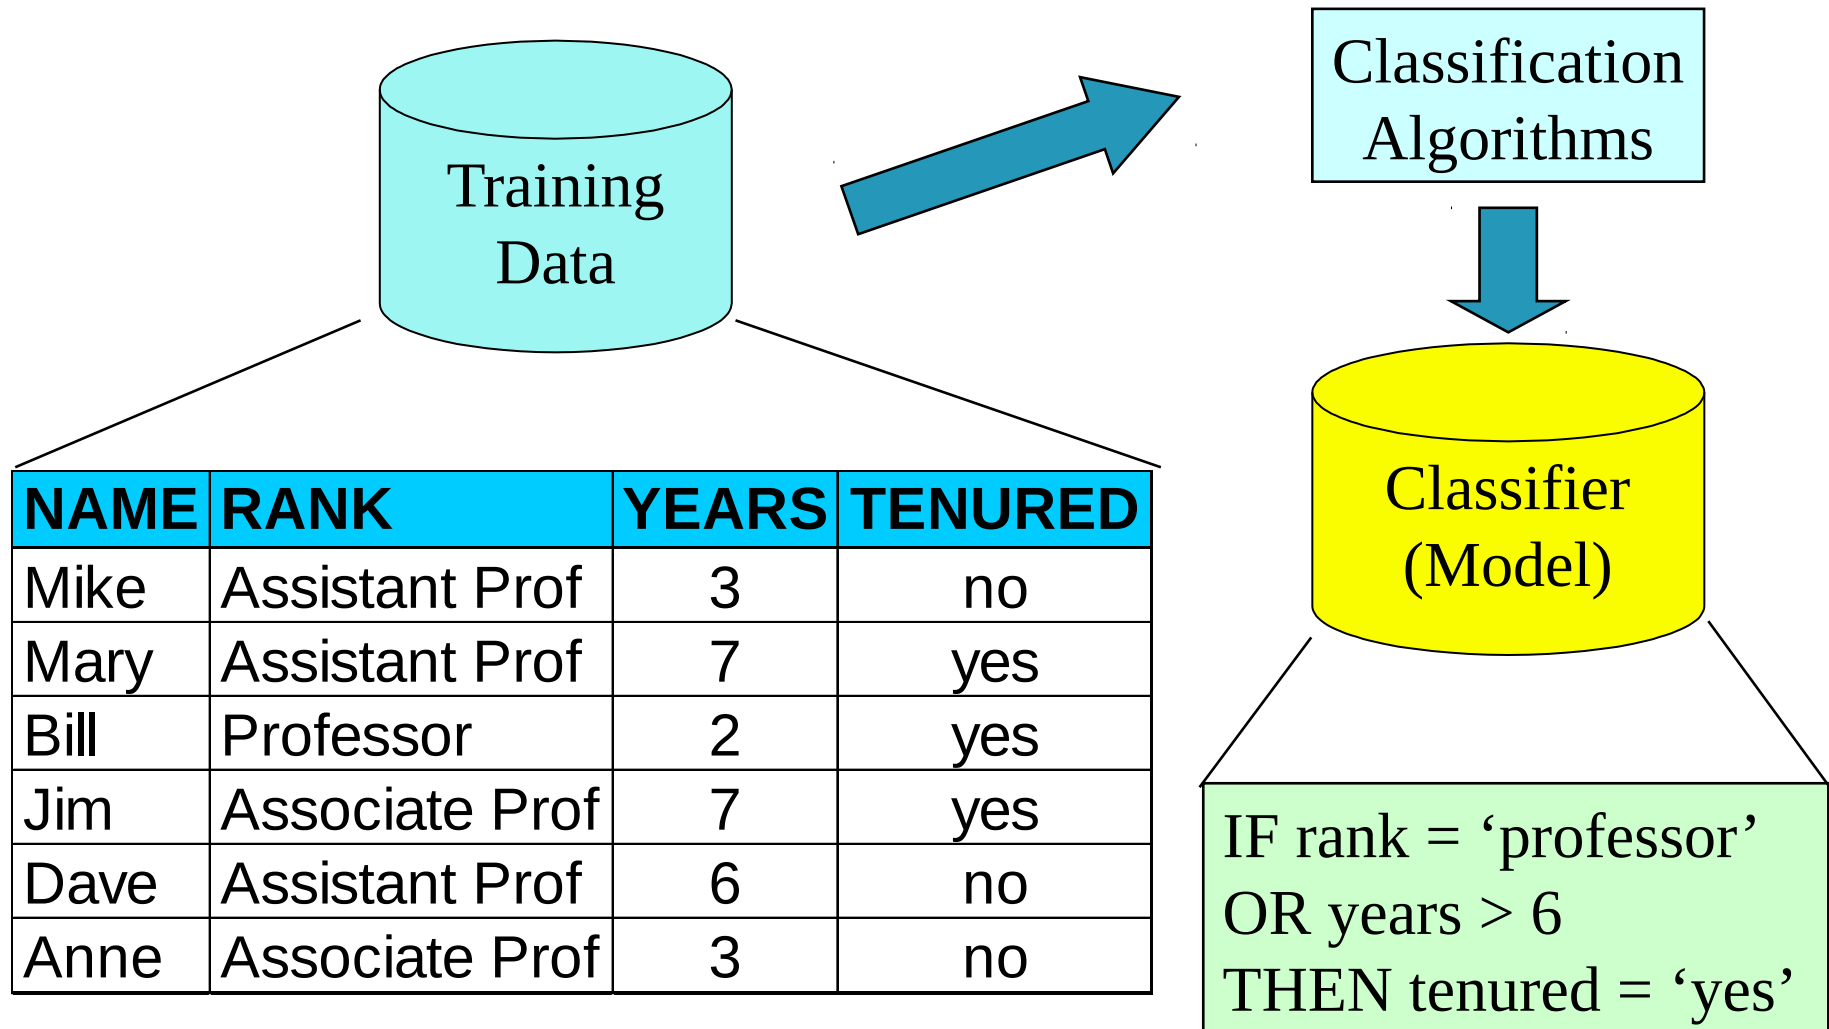

- **Classification**
  - predicts categorical class labels (discrete or nominal)
  - classifies data (constructs a model) based on the training set and the values (**class labels**) in a classifying attribute and uses it in classifying new data
- **Numeric Prediction**
  - models continuous-valued functions, i.e., predicts unknown or missing values
- Typical applications
  - Credit/loan approval:
  - Medical diagnosis: if a tumor is cancerous or benign
  - Fraud detection: if a transaction is fraudulent
  - Web page categorization: which category it is

# Classification—A Two-Step Process

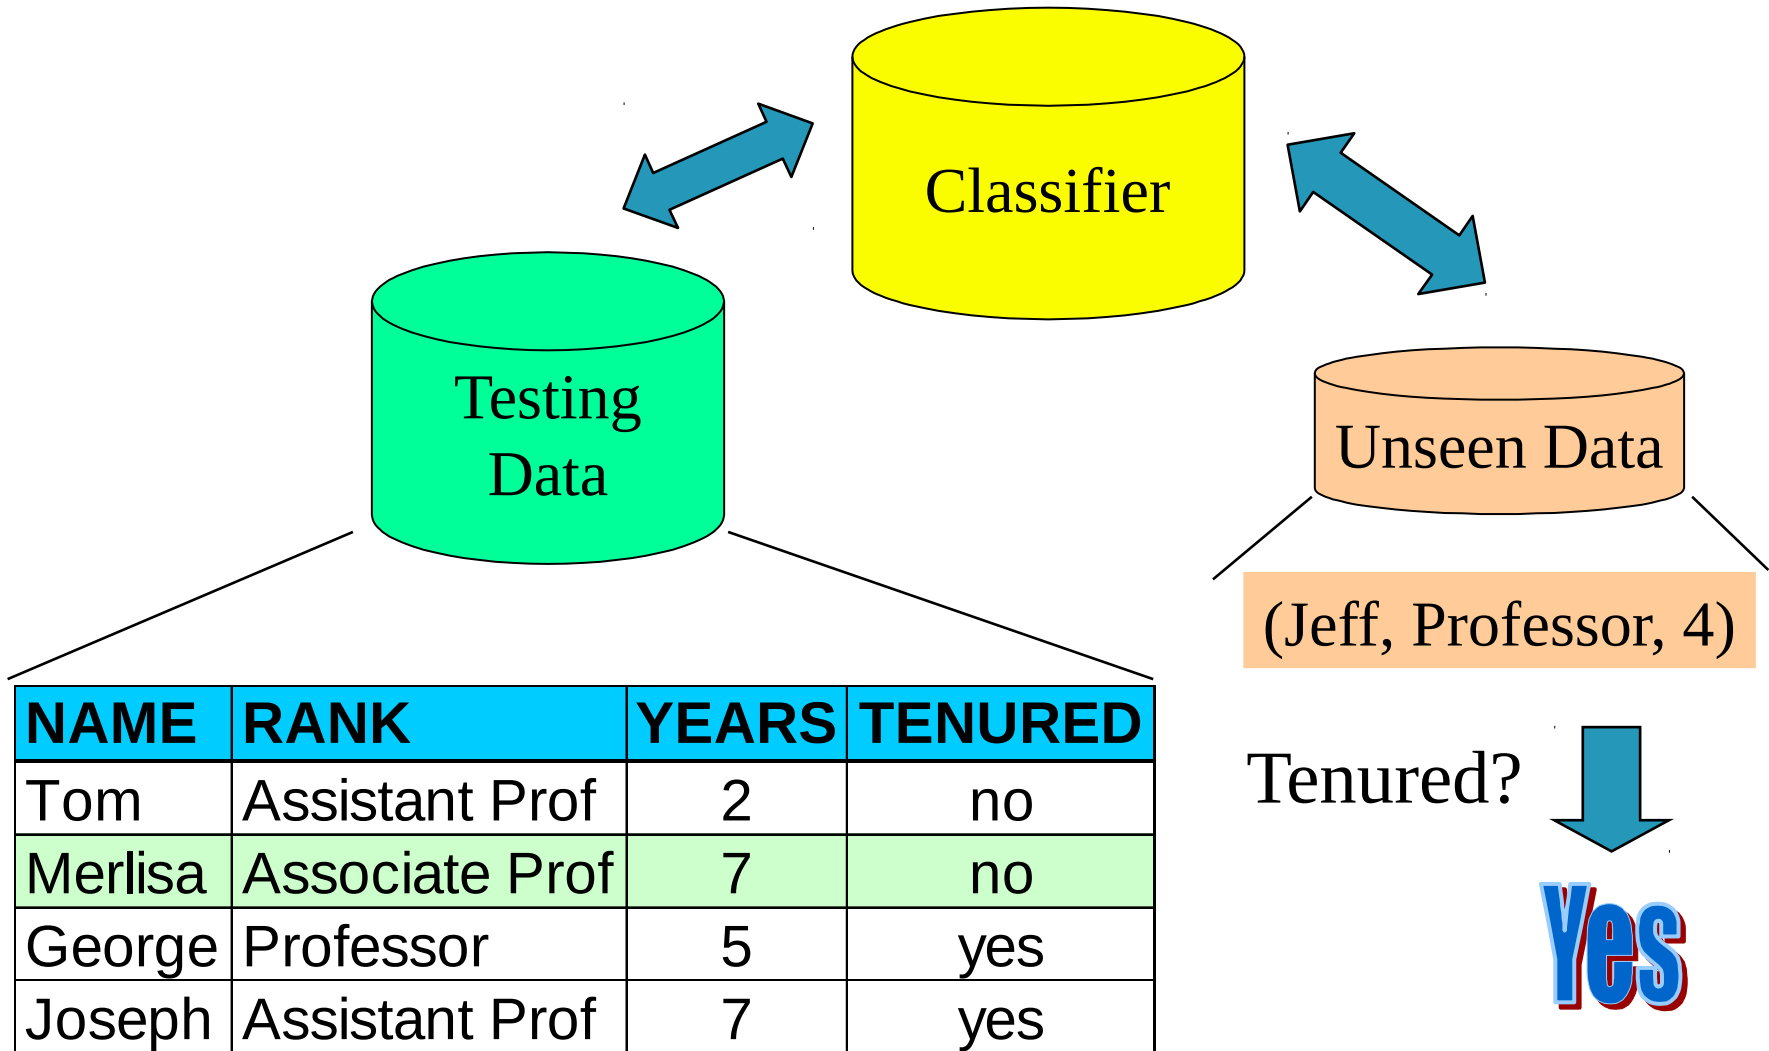

---

- **Model construction**: describing a set of predetermined classes
  - Each tuple/sample is assumed to belong to a predefined class, as determined by the **class label attribute**
  - The set of tuples used for model construction is **training set**
  - The model is represented as classification rules, decision trees, or mathematical formulae
- **Model usage**: for classifying future or unknown objects
  - **Estimate accuracy** of the model
    - The known label of test sample is compared with the classified result from the model
    - **Accuracy** rate is the percentage of test set samples that are correctly classified by the model
    - **Test set** is independent of training set (otherwise overfitting)
  - If the accuracy is acceptable, use the model to **classify data** tuples whose class labels are not known

# Process (1): Model Construction (learning)

# Process (2): Using the Model in Prediction (classification)

# Classification techniques

---

- Information-gain based methods
  - decision tree induction
- Classification probability based methods
  - Bayesian classification
- Geometry based methods
  - Support Vector Machines
- Other approaches (e.g. ANN)

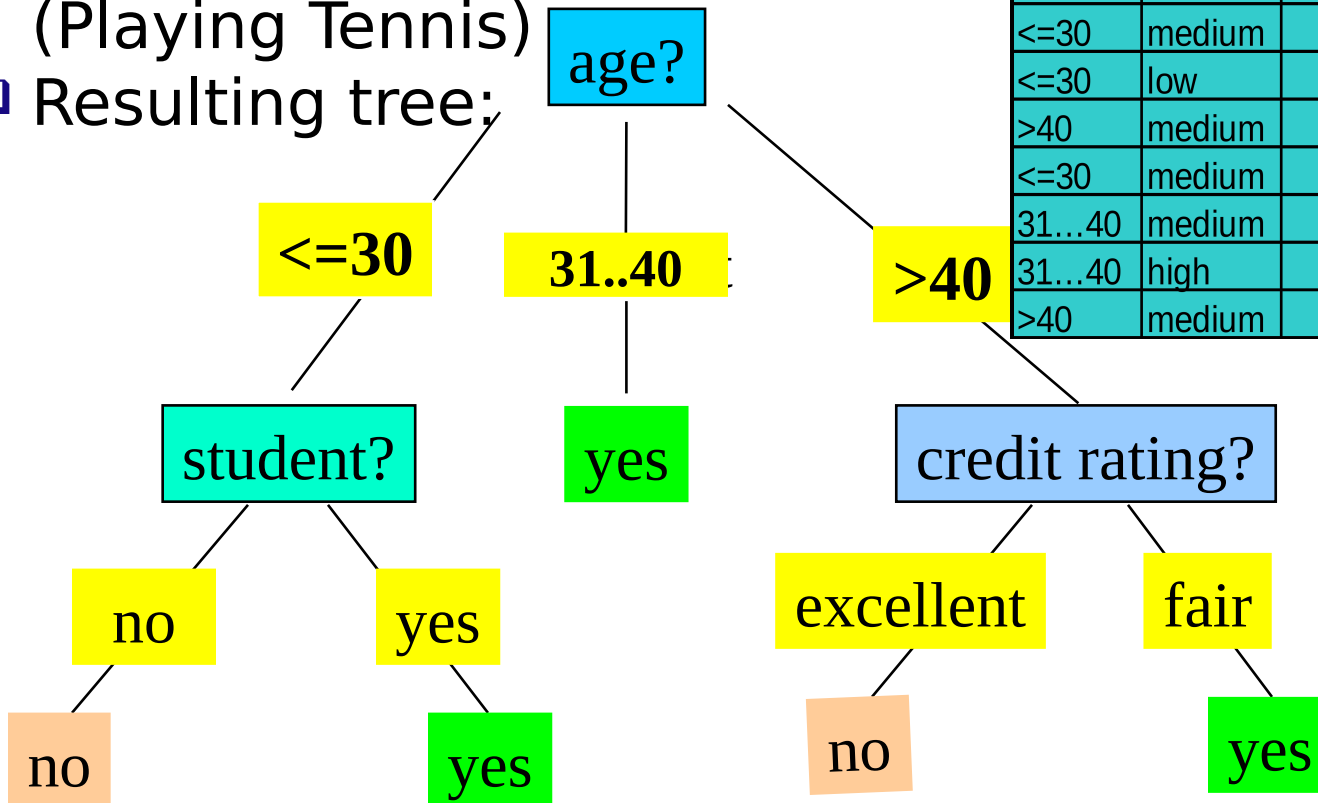

# Classification methods

---

- Classification: Basic Concepts
- Decision Tree Induction 
- Bayes Classification Methods
- Support Vector Machines
- Model Evaluation and Selection
- *Rule-Based Classification*
- *Techniques to Improve Classification Accuracy: Ensemble Methods*

# Decision Tree Induction: An Example

- Training data set:  
Buys\_computer
- The data set follows an example of Quinlan's ID3 (Playing Tennis)
- Resulting tree:

age	income	student	credit rating	buys computer
<=30	high	no	fair	no
<=30	high	no	excellent	no
31...40	high	no	fair	yes
>40	medium	no	fair	yes
>40	low	yes	fair	yes
>40	low	yes	excellent	no
31...40	low	yes	excellent	yes
<=30	medium	no	fair	no
<=30	low	yes	fair	yes
>40	medium	yes	fair	yes
<=30	medium	yes	excellent	yes
31...40	medium	no	excellent	yes
31...40	high	yes	fair	yes
>40	medium	no	excellent	no

# Algorithm for Decision Tree Induction

---

- Basic algorithm (a greedy algorithm)
  - Tree is constructed in a **top-down recursive divide-and-conquer manner**
  - At start, all the training examples are at the root
  - Attributes are categorical (if continuous-valued, they are discretized in advance)
  - Examples are partitioned recursively based on selected attributes
  - Test attributes are selected on the basis of a heuristic or statistical measure (e.g., **information gain**)

# Algorithm for Decision Tree Induction

---

- Conditions for stopping partitioning
  - All samples for a given node belong to the same class (pure partition)
  - There are no remaining attributes for further partitioning – **majority voting** is employed for classifying the leaf
  - There are no samples left
- Selection criteria:
  - Information gain (ID3)
  - Gain ratio (C4.5)
  - Gini index (CART)

# Attribute Selection Measure: Information Gain (ID3/C4.5)

- Let  $p_i$  be the probability that an arbitrary tuple in  $D$  belongs to class  $C_i$ , estimated by  $|C_{i,D}|/|D|$
- Recall: number of “binary tests” needed to find the class of a tuple in  $C_i$  is  $-\log_2(p_i)$

- **Expected information** (entropy) needed to classify a tuple in  $D$ :

$$Info(D) = - \sum_{i=1}^m p_i \log_2(p_i)$$

- **Information** needed (after using  $A$  to split  $D$  into  $v$  partitions) to classify  $D$ :

$$Info_A(D) = \sum_{j=1}^v \frac{|D_j|}{|D|} \times Info(D_j)$$

- **Information gained** by branching on attribute  $A$

$$Gain(A) = Info(D) - Info_A(D)$$

# Attribute Selection: Information Gain

age	income	student	credit_rating	PC	
<=30	high	no	fair	no	
<=30	high	no	excellent	no	
31...40	high	no	fair	yes	
>40	medium	no	fair	yes	
>40	low	yes	fair	yes	
>40	low	yes	excellent	no	
31...40	low	yes	excellent	yes	
<=30	medium	no	fair	no	
<=30	low	yes	fair	yes	
>40	medium	yes	fair	yes	
<=30	medium	yes	excellent	yes	
31...40	medium	no	excellent	yes	
31...40	high	yes	fair	yes	
>40	medium	no	excellent	no	

# Attribute Selection: Information Gain

- Class Y: buys\_computer = "yes"
- Class N: buys\_computer = "no"

$$Info(D) = I(9,5) = -\frac{9}{14} \log_2\left(\frac{9}{14}\right) - \frac{5}{14} \log_2\left(\frac{5}{14}\right) = 0.940$$

age	Y <sub>i</sub>	N <sub>i</sub>	I(p <sub>i</sub> , n <sub>i</sub> )
<=30	2	3	0.971
31...40	4	0	0
>40	3	2	0.971

$\frac{5}{14} I(2,3)$  means "age <=30" has 5 out of 14 samples, with 2 yes'es and 3 no's. Hence

$$Info_{age}(D) = \frac{5}{14} I(2,3) + \frac{4}{14} I(4,0) + \frac{5}{14} I(3,2) = 0.694$$

and therefore  $Gain(age) = 0.940 - 0.694 = 0.246$  bits.

Similarly  $Gain(income) = 0.029$  bits ...

$$Info(D) = -\sum_{i=1}^m p_i \log_2(p_i) \qquad Info_A(D) = \sum_{j=1}^v \frac{|D_j|}{|D|} \times Info(D_j)$$

$$Gain(A) = Info(D) - Info_A(D)$$

# Computing Information-Gain for Continuous-Valued Attributes

---

- Let attribute A be a continuous-valued attribute
- Must determine the *best split point* for A
  - Sort the value A in increasing order
  - Typically, the midpoint between each pair of adjacent values is considered as a possible *split point*:  $(a_i + a_{i+1})/2$
  - The point with the *minimum expected information requirement* for A is selected as the split-point for A
- Split:D1 is the set of tuples in D satisfying  $A \leq \text{split-point}$ , and D2 is the set of tuples in D satisfying  $A > \text{split-point}$

# Gain Ratio for Attribute Selection (C4.5)

- Information gain measure is biased towards attributes with a large number of values
- C4.5 (a successor of ID3) uses gain ratio to overcome the problem (normalization to information gain)

$$SplitInfo_A(D) = - \sum_{j=1}^v \frac{|D_j|}{|D|} \times \log_2 \left( \frac{|D_j|}{|D|} \right)$$

$$\begin{aligned} Info(D) &= - \sum_{i=1}^m p_i \log_2(p_i) \\ Info_A(D) &= \sum_{j=1}^v \frac{|D_j|}{|D|} \times Info(D_j) \\ Gain(A) &= Info(D) - Info_A(D) \end{aligned}$$

- GainRatio(A) = Gain(A) / SplitInfo(A)
- Ex.

$$SplitInfo_{income}(D) = -\frac{4}{14} \times \log_2\left(\frac{4}{14}\right) - \frac{6}{14} \times \log_2\left(\frac{6}{14}\right) - \frac{4}{14} \times \log_2\left(\frac{4}{14}\right) = 1.557$$

- gain\_ratio(income) = 0.029/1.557 = 0.019
- The attribute with the maximum gain ratio is selected as the splitting attribute

# Gini Index (CART, IBM IntelligentMiner)

- If a data set  $D$  contains examples from  $n$  classes, gini index,  $gini(D)$  is defined as

$$gini(D) = 1 - \sum_{j=1}^n p_j^2$$

where  $p_j$  is the relative frequency of class  $j$  in  $D$

- If a data set  $D$  is split on  $A$  into two subsets  $D_1$  and  $D_2$ , the gini index  $gini_A(D)$  is defined as

$$gini_A(D) = \frac{|D_1|}{|D|} gini(D_1) + \frac{|D_2|}{|D|} gini(D_2)$$

- Reduction in Impurity:

$$\Delta gini(A) = gini(D) - gini_A(D)$$

- The attribute provides the smallest  $gini_{split}(D)$  (or the largest reduction in impurity) is chosen to split the node (*need to enumerate all the possible splitting points for each attribute*)

# Computation of Gini Index

- Ex. D has 9 tuples in buys\_computer = “yes” and 5 in “no”:  $5/14 * I(2,3)$

$$gini_{income \in \{low, medium\}}(D) = \left(\frac{10}{14}\right) Gini(D_1) + \left(\frac{4}{14}\right) Gini(D_2)$$

- Suppose the attribute income partitions D into 10 in  $D_1$ : {low, medium} and 4 in  $D_2$

$$\begin{aligned} &= \frac{10}{14} \left( 1 - \left(\frac{7}{10}\right)^2 - \left(\frac{3}{10}\right)^2 \right) + \frac{4}{14} \left( 1 - \left(\frac{2}{4}\right)^2 - \left(\frac{2}{4}\right)^2 \right) \\ &= 0.443 \\ &= Gini_{income \in \{high\}}(D). \end{aligned}$$

$Gini_{\{low, high\}}$  is 0.458;  $Gini_{\{medium, high\}}$  is 0.450. Thus, split on the {low, medium} (and {high}) since it has the lowest Gini index

# Computation of Gini Index

---

- All attributes are assumed continuous-valued
- May need other tools, e.g., clustering, to get the possible split values
- Can be modified for categorical attributes

# Comparing Attribute Selection Measures

---

- The three measures, in general, return good results but
  - **Information gain:**
    - biased towards multivalued attributes
  - **Gain ratio:**
    - tends to prefer unbalanced splits in which one partition is much smaller than the others
  - **Gini index:**
    - biased to multivalued attributes
    - has difficulty when # of classes is large
    - tends to favor tests that result in equal-sized partitions and purity in both partitions

# Other Attribute Selection Measures

- CHAID: a popular decision tree algorithm, measure based on  $\chi^2$  test for independence
- C-SEP: performs better than i. gain and gini index in certain cases
- G-statistic: has a close approximation to  $\chi^2$  distribution
- MDL (Minimal Description Length) principle (i.e., the simplest solution is preferred): the best tree is one that requires the fewest # of bits to both (1) encode the tree, and (2) encode the exceptions (misclassifications)
- Multivariate splits (partition based on multiple variable combinations) → CART: finds multivariate splits based on a linear comb. of attrs. (*feature construction*)
- Which attribute selection measure is the best?
  - Most give good results, none is significantly superior

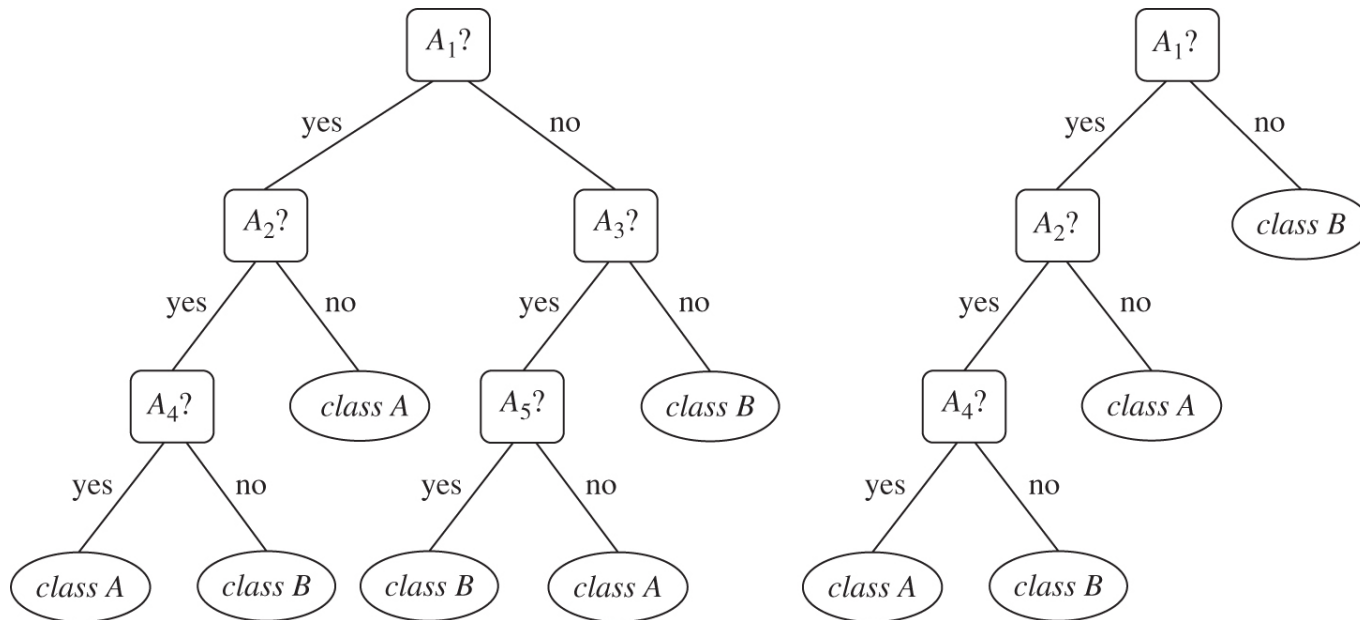

# Overfitting and Tree Pruning

---

- Overfitting: An induced tree may overfit the training data
  - Too many branches, some may reflect anomalies due to noise or outliers
  - Poor accuracy for unseen samples
  - Try to balance cost complexity and information gain
- Two approaches to avoid overfitting
  - Prepruning: *Halt tree construction early*- do not split a node if this would result in the goodness measure falling below a threshold
    - Difficult to choose an appropriate threshold
  - Postpruning: *Remove branches* from a “fully grown” tree—get a sequence of progressively pruned trees
    - Use a test set to decide which is “best pruning”

# Overfitting and Tree Pruning

Say this case  
is infrequent

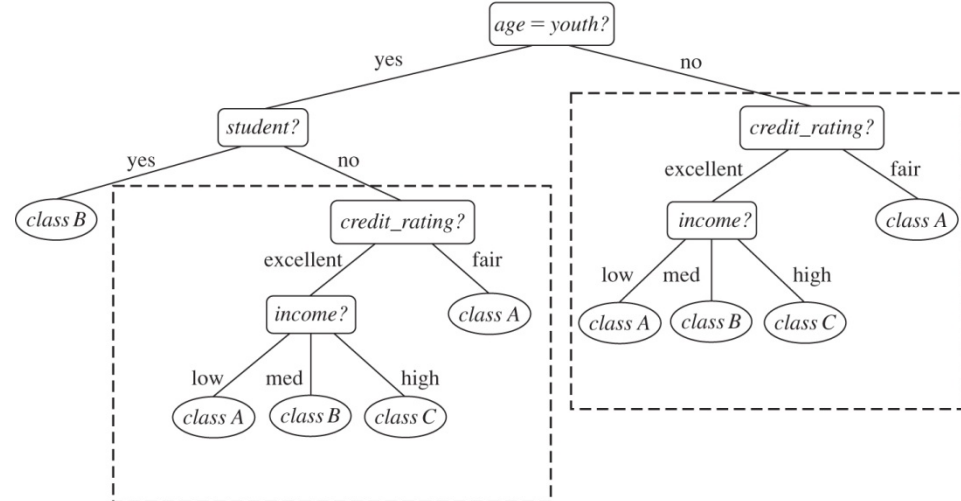

# Repetition and Replication

(a) subtree **repetition**, where an attribute is repeatedly tested along a given branch of the tree (e.g., *age*)

(b) subtree **replication**, where duplicate subtrees exist within a tree (e.g., the subtree headed by the node “*credit\_rating?*”)

(a)

(b)

# Classification in Big Data

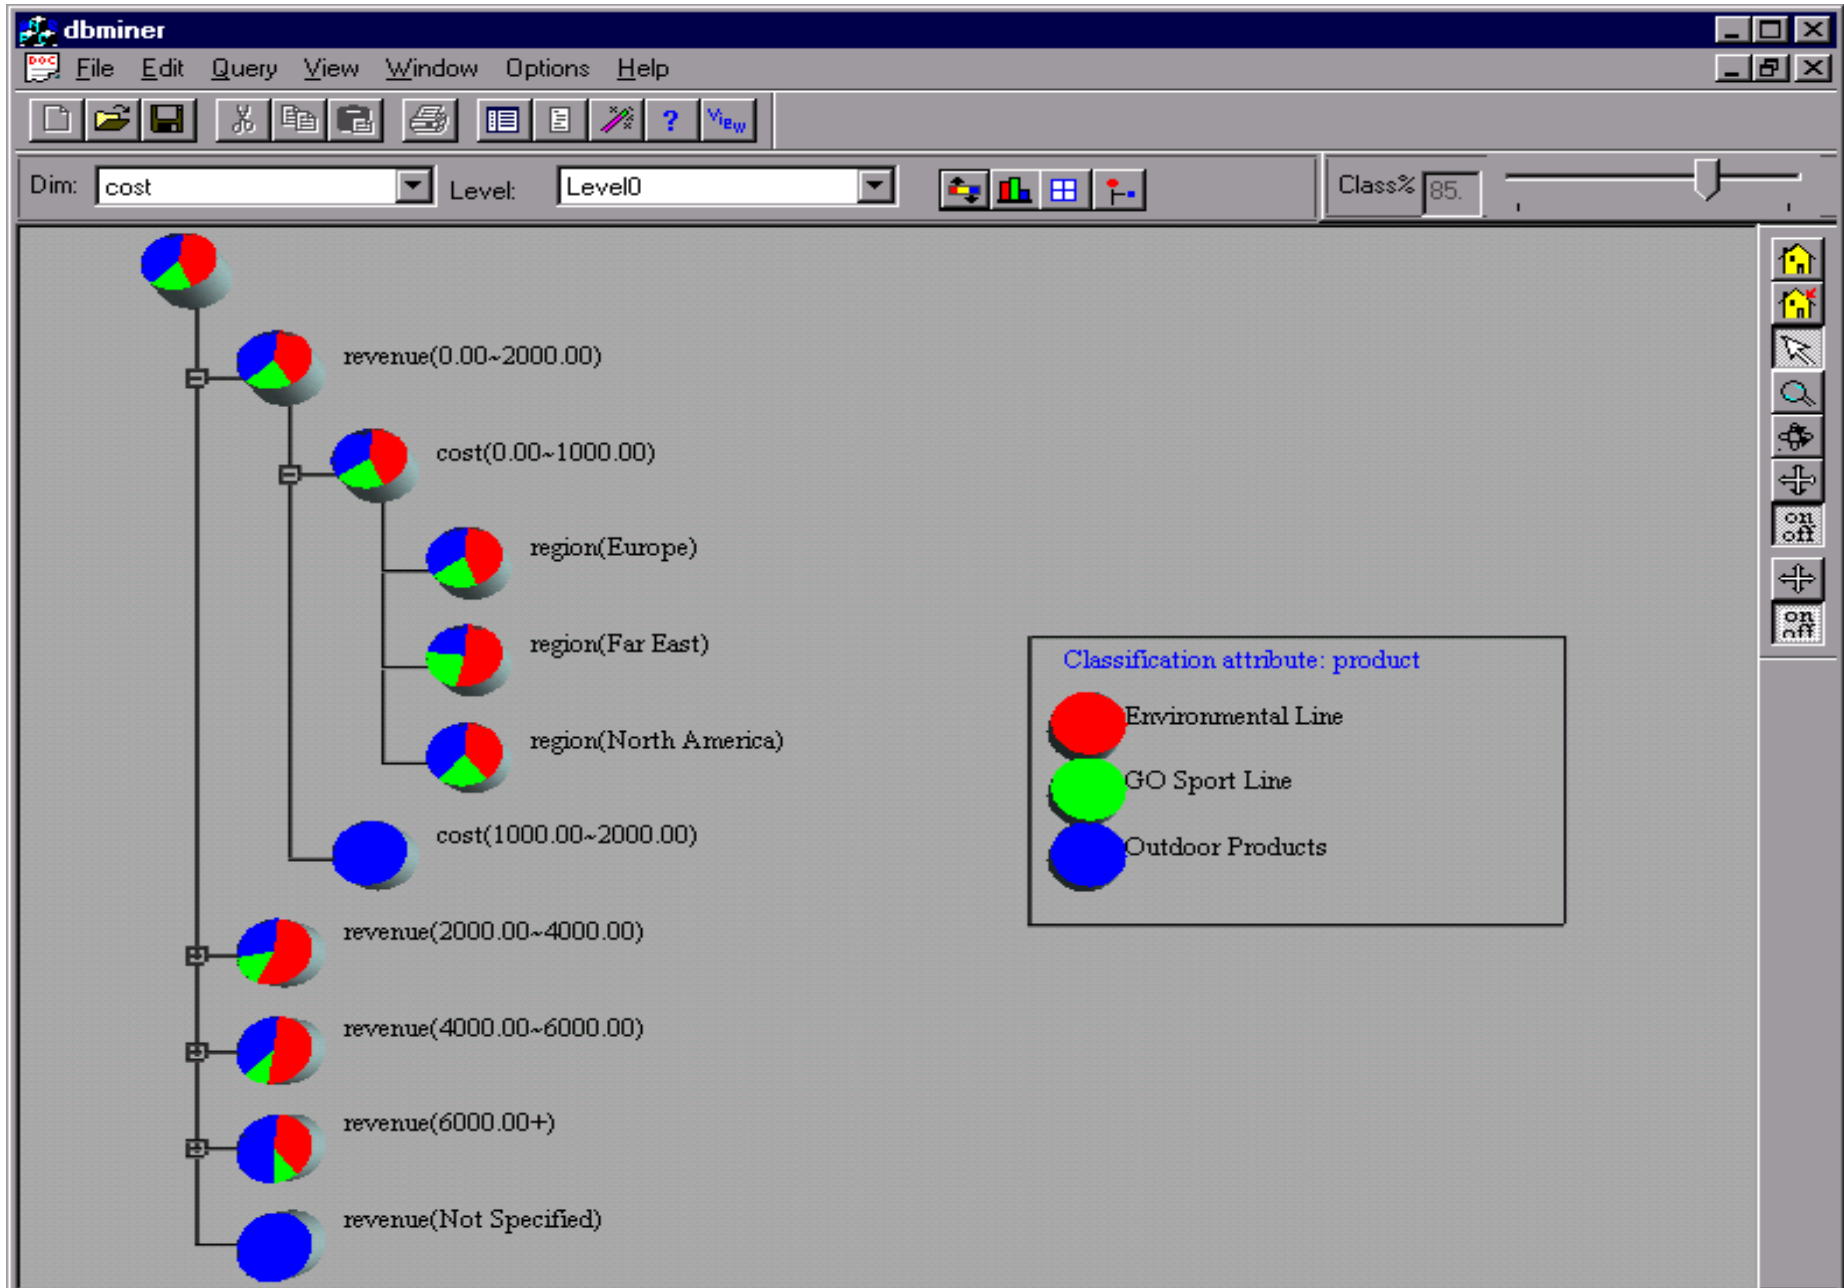

- Classification—a classical problem extensively studied by statisticians and machine learning researchers
- Scalability: Classifying data sets with millions of examples and hundreds of attributes with reasonable speed
- Why is decision tree induction popular?
  - relatively faster learning speed (than other classification methods)
  - convertible to simple and easy to understand classification rules
  - can use SQL queries for accessing databases
  - comparable classification accuracy with other methods
- **RainForest** (VLDB'98 — Gehrke, Ramakrishnan & Ganti)
  - Builds an AVC-list (attribute, value, class label)

# BOAT (Bootstrapped Optimistic Algorithm for Tree Construction)

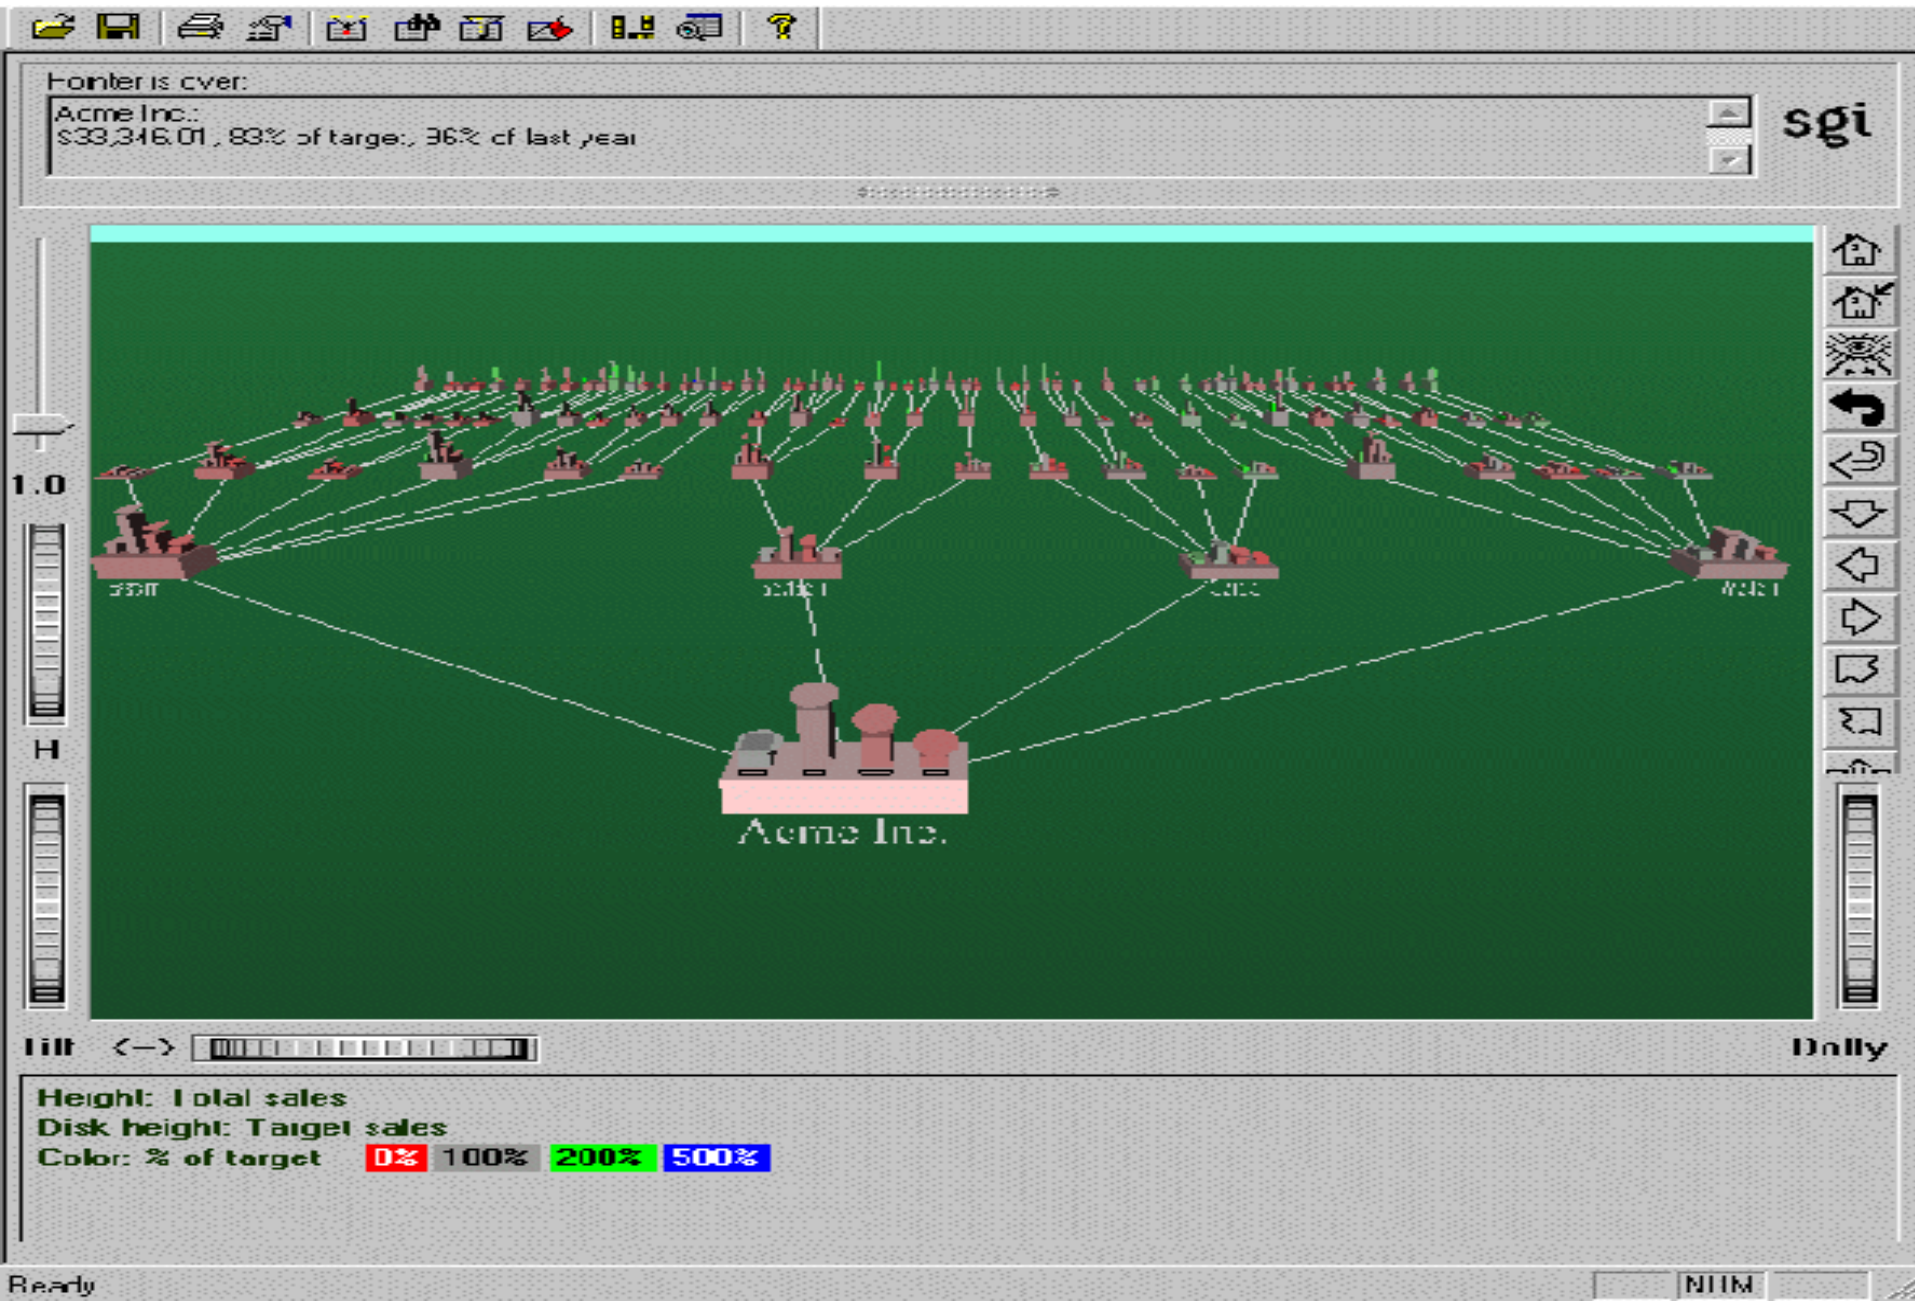

---

- Use a statistical technique called *bootstrapping* to create several smaller samples (subsets), each fits in memory
- Each subset is used to create a tree, resulting in several trees
- These trees are examined and used to construct a new tree  $T'$ 
  - It turns out that  $T'$  is very close to the tree that would be generated using the whole data set together
- Adv: requires only two scans of DB, an incremental alg.
