# Lecture XIII: A game of life

# A game of life

In 1970, J.H. Conway proposed his Game of Life, a simulation on a 2D grid:

- ① Every cell can be *alive* or *dead*: the game start with a population of alive cells (*seed*)
- ② any alive cell with less of 2 alive neighbours dies (*underpopulation*)
- ③ any alive cell with more than 3 alive neighbours dies (*overpopulation*)
- ④ any dead cell with exactly 3 alive neighbours becomes alive (*reproduction*)

The game is surprisingly rich: many mathematicians, computer scientists, biologists. . . spent their careers on the emerging patterns!

# Life forms

There are names for many “life forms”: *still lifes*, *oscillators*, *starships*. . .

A famous starship is the glider:

The glider repeats itself in another position after 4 generations.

## Python implementation

PyQB  
Monga

To implement a Game of Life simulation in Python, we can:

- use a ndarray for the grid
- each cell contains 0 (dead) or 1 (alive)
- for simplicity we can add a “border” of zeros

0	0	0	0	0
0	1	1	1	0
0	1	0	1	0
0	1	1	0	0
0	0	0	0	0

110

## Avoid loops

PyQB  
Monga

For a 1-D array X

0	1	1	0	1	0
---	---	---	---	---	---

All the neighbours on the right X[2:]

0	1	1	0	1	0
---	---	---	---	---	---

All the neighbours on the left X[:-2]

What does  $X[2:] + X[:-2]$  represent? The sum is (yellow) element by (yellow) element, the result is: [1,1,2,0]  
Can you think to a similar solution for the 2-D case?

111

## Avoid loops

PyQB  
Monga

0	0	0	0	0	0
0	0	1	0	0	0
0	0	0	1	0	0
0	1	1	1	0	0
0	0	0	0	0	0
0	0	0	0	0	0

X[1:-1, 2:]

0	0	0	0	0	0
0	0	1	0	0	0
0	0	0	1	0	0

112

## Avoid loops

PyQB  
Monga

X					
0	0	0	0	0	0
0	0	1	0	0	0
0	0	0	1	0	0
0	1	1	1	0	0
0	0	0	0	0	0
0	0	0	0	0	0

N					
0	0	0	0	0	0
0	1	1	2	1	0
0	3	5	3	2	0
0	1	3	2	2	0
0	2	3	2	1	0
0	0	0	0	0	0

X == 1

N > 3

Death by overpopulation:  $X[(X == 1) \& (N > 3)] = 0$   
(empty in this case!)
