# Lecture V: Functions

PyQB

Monga

Functions

## A function computes a result

- Returns a useful result

```
def concat_with_a_space(string1, string2):
    return string1 + ' ' + string2

# string1 is the _formal_ parameter
# 'foo' is the _actual_ parameter (like an assignment string1 = 'foo')
print(concat_with_a_space('foo', 'bar'))
```

- Return None

```
def repeated_print(string, repetitions):
    for i in range(0, repetitions):
        print(string)

repeatedPrint('Hello, world!', 3)
```

- Recursive call:

```
def repeatedPrint(string, repetitions):
    if repetitions > 0:
        print(string)
        repeatedPrint(string, repetitions - 1)

repeatedPrint('Hello, world!', 3)
```

Functions

## Functions are objects too

One can assign functions to variables:

```
def cube(x: int) -> int:
    square = x * x
    return square * x
```

```
mycube = cube
```

```
print(mycube(3))
print(type(mycube))
```

And short functions can even be expressed as literal expressions (lambda expressions)

```
cube = lambda y: y*y*y
```

## Naming helps solving

## Describe the moves for a solution

PyQB

Monga

Functions

Recursive thinking is a powerful problem solving technique and it can be translated to Python thanks to recursive calls.

Hanoi moves  $A \rightarrow C$ :

- In  $A$  there is just one disk: move it to  $C$
- Otherwise in  $A$  there are  $n$  disks ( $> 1$ ):
  - **leap of faith!** I suppose to know the moves needed to move  $n - 1$  disk; then
    - apply this (supposed) solution to move  $n - 1$  disks from  $A$  to  $B$  (leveraging on  $C$ , empty, as the third pole)
    - move the last disk from  $A$  to  $C$
    - apply the (supposed) solution to move  $n - 1$  disks from  $B$  to  $C$  (leveraging on  $A$ , now empty, as the third pole)

This implicit description solve the problem! Finding a non-recursive solution is possible but not that easy.

## In Python

PyQB

Monga

Functions

```
def hanoi(n: int, a_from: str, c_to: str,
        b_intermediate: str):
    if n == 1:
        print('Move 1 disk from ' + a_from + ' to ' + c_to)
        return
    hanoi(n - 1, a_from, b_intermediate, c_to)
    print('Move 1 disk from ' + a_from + ' to ' + c_to)
    hanoi(n - 1, b_intermediate, c_to, a_from)

hanoi(3, 'A', 'C', 'B')
```
