How science works

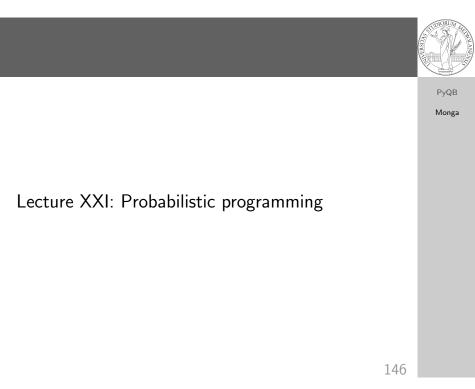

PyQB Monga

Describing one single "scientific method" is problematic, but a schema many will accept is:

- Imagine a hypothesis
- ② Design (mathematical/convenient) models consistent with the hypothesis
- ③ Collect experimental data
- ④ Discuss the fitness of data given the models

It is worth noting that the falsification of models is not *automatically* a rejection of hypotheses (and, more obviously, neither a validation).

The role of Bayes Theorem

In this discussion, a useful relationship between data and models is Bayes Theorem.

$$P(M, D) = P(M|D) \cdot P(D) = P(D|M) \cdot P(M)$$

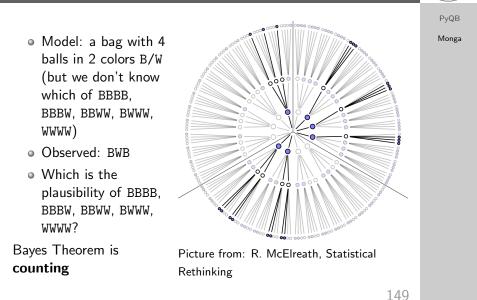

Therefore:

$$P(M|D) = \frac{P(D|M) \cdot P(M)}{P(D)}$$

The plausibility of the model given some observed data, is proportional to the number of ways data can be *produced* by the model and the prior plausibility of the model itself.

PyQB Monga

Simple example

Classical binomial example

PyQB Monga

- Which is the proportion p of water covering Earth? The models are indexed by the float 0
- Given *p*, the probability of observing some W,L in a series of **independent random observations** is:
- $P(W, L|p) = \frac{(W+L)!}{W! \cdot L!} p^W \cdot (1-p)^L$ (binomial distribution).
- Do we have an initial (prior) idea?
- Make observations, apply Bayes, update prior!

PyQB

Monga

This Bayesian strategy is (conceptually) easy to transform in a computational process.

- Code the models
- ② Run the models
- 3 Compute the plausibility of the models based on observed data

150

A conventional way of expressing the model

PyQB Monga

 $W \sim Binomial(W + L, p)$ $p \sim Uniform(0, 1)$

Probabilistic programming is systematic way of coding this kind of models, combining predefined statistical distributions and Monte Carlo methods for computing the posterior plausibility of parameters.

In principle you can do it by hand

PyQB Monga

def dbinom(success: int, size: int, prob: float) -> float:

fail = size - success
return np.math.factorial(size)/(np.math.factorial(success)*np.math.factorial(fail))*p
→ rob**success*(1-prob)**(fail)

W, L = 7, 3 # for example 'WWWLLWWLWW'
p_grid = np.linspace(start=0, stop=1, num=20)
prior = np.ones(20)/20

likelihood = dbinom(W, n=W+L, p=p_grid)

unstd_posterior = likelihood * prior

posterior = unstd_posterior / unstd_posterior.sum()

Unfeasible with many variables!
