Lecture VII: Composite objects

Simple and composite objects

- `ints` `floats` `bools` are simple objects: they have no “parts”
- Strings are an example of composite objects since it is possible to consider also the characters: a `str` is a sequence of single characters; an important (simplifying) property: they are `immutable`
- Generic `immutable` sequences (with elements of any type) are called `tuples` (`tuple`): `(1, 2, 'foo')` `(1,)`
- Generic `mutable` sequences (with elements of any type) are called `lists` (`list`): `[1, 2, 'foo']` `[1]`
`[1,2].append(3)`

Tuples and lists

Mutability

Immutable objects are simpler to use:

```
x = (1, 2, 3)
y = x
```

```
x = (10, 20, 30) # x refers to a new object, since the
↳ old cannot be changed
print(x, y)
```

Mutable ones require some caution:

```
x = [1, 2, 3]
y = x
```

```
x[0] = 10 # both x and y refer to a changed object
print(x, y)
```

```
x = [100, 200, 300]
print(x, y)
z = x.copy() # a copy not the same object
```

Composite
objects

Tuples and lists

- Write a function `middle(L: list[int]) -> int` which takes a list L as its argument, and returns the item in the middle position of L . (In order that the middle is well-defined, you should assume that L has odd length.) For example, calling `middle([8, 0, 100, 12, 1])` should return 100, since it is positioned exactly in the middle of the list.
(`assert` is a useful tool to check assumptions — known as **preconditions** — are indeed true)
- Define a function `prod(L: list[int])` which returns the product of the elements in a list L .
