# Lecture XV: Matplotlib

# Matplotlib

When you have arrays with many data it is useful to have a way to display them graphically.

- The most popular is `matplotlib`  
<https://matplotlib.org/>
- Many other graphical frameworks (e.g., `seaborn`, `plotnine`) based on it
- Many, many possibilities to tune your graphics! It's hard to master every detail.
- Be careful: it can be used with two different styles.
  - ① The (preferred) object-oriented way: clean and rational, but a bit more verbose
  - ② The procedural way: mostly useful only for “throw-away” scripts, but for this reason more common in the examples you can find online

# Graphical output is an operating system service

PyQB

Monga

Matplotlib

Graphical commands

OO plotting

- Output is a service provided by the operating system: *textual* output is very standardized even across different platform, **graphics is not so stable**
- When you deal with graphical programs: expect installation headaches, portability glitches, etc.

# The OO style

PyQB

Monga

Matplotlib

Graphical commands

OO plotting

- You need always two objects: a `Figure` and a `Axes`
- plotting happens on axes, framed in a figure
- very flexible: you can add plots on the same axis, or you can have many axes collected in a single figure

# Basic example

```
import numpy as np
import matplotlib.pyplot as plt

x = np.linspace(-2*np.pi, 2*np.pi, 100)

fig, ax = plt.subplots()

ax.plot(x, np.sin(x))

fig.show()
```

# Many different types of charts

PyQB

Monga

Matplotlib

Graphical commands

OO plotting

If `ax` is a `Axes`

- Scatter-plots `ax.scatter`
- Bar-plots `ax.bar`
- Histograms `ax.hist`
- 2D `ax.imshow`

# Tweaks

PyQB

Monga

Matplotlib

Graphical commands

OO plotting

- add labels, legends, titles
- add a grid
- combine multiple plots on the same axis
- combine multiple axes on the same figure

# Save your pictures!

PyQB

Monga

Matplotlib

Graphical commands

OO plotting

A Figure can be saved in a file with `savefig`. You should keep in mind the difference between:

- bitmap formats (`png jpg ...`): the file is matrix of pixels
- vector formats (`svg pdf ...`): the file is a set of instructions to reproduce the picture, less portable but it can be magnified

# Using the notebook in a virtual environment

Since we are now interested in graphics, Jupyter notebooks can be very convenient to see pictures together with the code.

- ➊ We set up a virtual environment as usual
- ➋ With `pip install notebook` we have the Jupyter notebook machinery available
- ➌ I normally want to have also a clean `.py` file, since `.ipynb` do not play well with configuration management (`git`) and other command line tools like the type checker or `doctest`: thus I suggest to install `jupytext`; it needs a `jupytext.toml` text file telling `.ipynb` and `.py` files are **paired**, *i.e.*, they are kept synchronized.

```
# Always pair ipynb notebooks to py files
formats = "ipynb,py:percent"
```
- ➍ launch the notebook with `jupyter notebook`
